

# The Declining Middle:

## Political Reactions to Occupational Change

Thomas Kurer \*

May 30, 2019

This article investigates the political consequences of occupational change in times of rapid technological advancement and sheds light on the economic and cultural roots of right-wing populism. A growing body of research shows that the disadvantages of a transforming employment structure are strongly concentrated among semiskilled routine workers in the lower middle class. It is argued that individual employment trajectories and *relative* shifts in the social hierarchy are key to better understand recent political disruptions. A perception of relative economic decline among politically powerful groups – not their impoverishment – drives support for conservative and, especially, right-wing populist parties. Individual-level panel data from three post-industrial democracies and an empirical strategy tailored to the estimation of dynamic causal effects demonstrate this relationship. Additional evidence from original survey data lends credence to the proposed mechanism. The findings imply that "more welfare" will be an ineffective remedy against the ascent of right-wing populism.

---

\*Weatherhead Center for International Affairs, Harvard University. [tkurer@wcfia.harvard.edu](mailto:tkurer@wcfia.harvard.edu)

At least since the Industrial Revolution, pundits and the public alike have had a keen interest in the social and political consequences of economic modernization and the concomitant evolution of labor markets. Deindustrialization and globalization continued to transform the highly industrialized economies of Western Europe into post-industrial societies; and a rich literature has studied political implications of these processes (e.g. Kitschelt & McGann, 1995; Iversen & Cusack, 2000; Kriesi, Grande, Lachat, Dolezal, Bornschier & Frey, 2008; Rodrik, 2018; Colantone & Stanig, 2018).

In recent years, the most important factor behind occupational change has been technology (Oesch, 2013; Goos, Manning & Salomons, 2014; OECD, 2017). Rapid advances in automation and computerization push us into a new era where many existing skills and competencies become increasingly redundant. The disadvantages are not distributed uniformly, however, as contemporary innovations in technology affect distinct occupations in fundamentally different ways. Routine workers in the (lower) middle of the education and earnings distribution bear the brunt of workplace automation (Autor, Levy & Murnane, 2003). How does this politically influential group react to previously unknown level of vulnerability?

This article asks about the economic fundamentals behind recent political disruptions and examines the electoral consequences of the "hollowing of the middle" in post-industrial labor markets. Although observers have been quick to suggest that those "left behind" by economic modernization are at the root of widespread political dissatisfaction and rising anti-establishment rhetoric, we still lack a clear picture of the structural determinants. Only recently have researchers begun to uncover how a technology-induced transformation of the employment structure shapes political attitudes. While some argue that workers susceptible to automation will demand social security (Thewissen & Rueda, 2017), others who study vote choice emphasize an anti-incumbent (Frey, Berger & Chen, 2018) or a right-wing populist anti-establishment effect (Im, Mayer, Palier & Rovny, 2019; Anelli, Colantone & Stanig, 2019). The underlying mechanisms are not obvious, however, and hence it should not come as a surprise that other studies, which have difficulties to reveal clear associations between material interests and political reaction, conclude that non-economic

motives must prevail over economic ones (Inglehart & Norris, 2016). As a result, contemporary research controversially discusses the cultural and economic roots of right-wing populism, Trump, Brexit, and changing patterns of mass opinion more generally (Gidron & Hall, 2017; Mutz, 2018; Antonucci, Horvath, Kutiyski & Krouwel, 2017; Rooduijn & Burgoon, 2018).

We contribute to this debate by studying routine workers' political reaction to increasingly bleak labor market prospects in the face of rapid technological progress. Routine work still accounts for about 25-30% of the work force in advanced capitalist democracies and is found in both blue- and white-collar sectors. It has long been a highly respected kind of labor that guaranteed a decent standard of living and prospects of upward mobility (Nachtwey, 2016). Yet, the particular vulnerability to new digital technology fundamentally changes this outlook.

Interestingly, recent research has shown that the strong aggregate decline in routine work does not go hand in hand with similarly impressive replacement rates on the individual level. Technological change is a very gradual process and a majority of routine workers susceptible to automation manages to cling to their jobs until (early) retirement (Cortes, 2016; Kurer & Gallego, 2019). The main driver behind the decline is a compositional effect due to higher exit rates and lower entry rates. Superficially considered, one could thus mistake routine workers' economic situation as stable. However, stability (or stagnation) in an increasingly hostile economic environment is of limited satisfaction when other parts of society are catching up or pulling away.

Routine workers' situation in an increasingly automated world of work thus provides an ideal case to disentangle the political consequences of *fearing* as opposed to *experiencing* economic adversity. In contrast to existing work, this article does not focus on the usual snap-shot indicators of absolute economic hardship but brings different employment trajectories and *relative* shifts in economic well-being into the spotlight. While routine workers all face similar initial threats from automation, the materialized occupational trajectories are diverse and strongly differ in their material implications. We will argue that

distinct employment trajectories crucially shape the relative salience of economic and non-economic demands among voters. While surviving in a sour occupational environment (relative decline) increases the demand for status maintenance and activates nostalgic, socially conservative predispositions, actually losing a job in routine work (absolute decline) prompts an economic response.

With that aim, we leverage individual-level panel data from Germany, Switzerland and the United Kingdom to analyze the effect of differential employment trajectories on routine workers' political behavior. The analysis employs an empirical strategy tailored to the investigation of dynamic processes such as repeated occupational transitions, so called marginal structural models, to estimate the causal effect of three distinct paths out of routine work. The core result of this paper demonstrates that it is a perception of relative decline and concomitant anxiety about one's position in society — not poverty or acute material hardship — that drives support for right-wing populist parties.

The presented theoretical argument and empirical findings provide a novel and more nuanced reading of the economic roots of populism. We help reconcile the contradictions manifest in existing research by relying on a relational understanding of economic disadvantage (see also Burgoon, van Noort, Rooduijn & Underhill, 2018). Extending the focus beyond the usual indicators of material hardship shows that fundamentally economic processes like changing labor markets might very well result in non-economic (or not purely economic) political responses.

Our more nuanced interpretation of the structural drivers behind right-wing populism has immediate policy implications. When relative rather than absolute economic decline drives socially conservative resentment, the often-stated remedy of "more welfare" will be an insufficient response to satisfy exposed workers and hence an ineffective remedy to counter the ascent of right-wing populist movements.

# Occupational Trajectories of Routine Workers

The theoretical framework of this paper follows influential work in labor economics, which builds on a simplified model economy with three task groups (Autor et al., 2003; Spitz-Oener, 2006; Cortes, 2016). As *routineness* is the defining feature of susceptibility to automation (Autor et al., 2003), we focus on the characteristics of an occupation in terms of task content rather than skill level. At the center of interest is the group of routine workers. By routine, we do not mean trivial or mundane tasks. The performed routine tasks can be relatively demanding and might require considerable training but, once the necessary rules and procedures are internalized, they are characterized by a certain repetitiveness that follows a given protocol. This repetitive trait makes such tasks "codifiable" and hence susceptible to automation (Acemoglu & Autor, 2011). Many blue-collar jobs in factories and handicraft belong to this category but also a significant part of basic white-collar work in administration, e.g. office clerks or customer service employees.

Two fundamentally different kinds of non-routine groups exist alongside routine employment. Non-routine cognitive work is characterized by non-repetitive, abstract and cognitively demanding analytical and interactive problem-solving tasks usually requiring higher education. Think of managerial and complex professional jobs, for example business managers, higher education teachers or civil engineers but also workers in the creative industry. In comparison, non-routine manual jobs lie at the other end of the skill distribution and are characterized by relatively simple but hard-to-automate tasks, oftentimes because they require personal interaction or hand-eye coordination (Goos & Manning, 2007). Most of these jobs are associated with low-skill service employment like taxi driving, food preparation, cleaning or sales.<sup>1</sup>

Table 1 presents descriptive information from the three countries analyzed below to confirm the notion of routine workers being a sizable group in the middle of the labor force.

---

<sup>1</sup>Many of those low-skilled jobs in the service sector will be threatened by automation in coming years, too. The focus of this study, however, is on the past and contemporary impact of technological change. The rather bleak forward-looking perspective, e.g. given by Frey and Osborne (2017), allows for interesting speculation about further political repercussions in the future but not for empirical analysis of the political consequences observed up to now.

Compared to non-routine manual (*M*) work, routine (*R*) jobs are characterized by more demanding educational requirements and, correspondingly, higher median wages. At the same time, non-routine cognitive (*C*) work is associated with even higher job quality as it clearly outperforms routine work in terms of both indicators. The two last columns confirm the core assumptions with respect to routineness and susceptibility to automation. As expected, routine occupations are strongly dominated by routine tasks as indicated by positive values in the Routine Task Intensity (RTI) index (Autor & Dorn, 2013), whereas both non-routine groups – irrespective of skill requirements – have negative average values. In line with the idea that computers are especially successful in substituting routine work, the prevalence of repetitive tasks in the middle group goes hand in hand with a distinctively higher replacement risk in the near future (Frey & Osborne, 2017).

TABLE 1: Descriptive Statistics per Country and Task Group

Country	Task Group	Share of Labor Force	Share Un-skilled	Share Female	Median Income	RTI	Autom. Risk
CH	C	48.3	4.6	41.5	5670	-0.656	0.222
	R	22.6	15.4	56.7	3683	1.519	0.841
	M	29.1	19.0	69.5	2492	-0.172	0.612
DE	C	35.0	5.9	43.7	2556	-0.654	0.251
	R	31.2	19.7	49.0	1600	1.157	0.788
	M	33.8	25.7	66.5	1100	-0.192	0.613
UK	C	33.7	5.8	44.2	1720	-0.744	0.231
	R	23.8	16.0	52.7	1051	1.547	0.842
	M	42.5	25.2	68.5	598	-0.071	0.621

Source: Country-specific panel data, pooled over time (see Table 2 for details on the sample). Task Groups: C = Non-routine cognitive, R = Routine, M = Non-routine manual. Median Income is in domestic currency. RTI is average value of the Routine Task Index (Autor & Dorn, 2013). RTI has been merged to individuals on the basis of occupation (ISCO88 2-digit). Automation Risk is the average value of the estimated probability of an occupation being replaced due to computerization (see Frey & Osborne, 2017). Correspondence tables have been used to merge these values, originally calculated for occupational groups based on the US Labor Department's Standard Occupational Classification (SOC), with European classifications of occupations (ISCO88 4-digit).

A major advantage of this influential theoretical approach for our paper is that it provides a parsimonious framework for routine workers' universe of potential occupational transi-

tions. Three conceptually distinct task groups and the additional possibility of becoming unemployed yield the following four occupational trajectories.

- Upgrading: Switch from routine job to non-routine cognitive job
- Surviving: Remain in routine job
- Downgrading: Switch from routine job to non-routine manual job
- Dropout: Lose routine job and unable to find a new job

Although routine workers face similar (initial) threats from automation, they vary in their exit options, that is, their capabilities to escape the contracting job opportunities in the middle. In the best case, now-redundant workers in routine jobs will be able to upgrade to non-routine cognitive jobs. On average, this transition will be accompanied by an increase in earnings, occupational prestige and job security. At the same time, the decline in routine work will force others to downgrade to non-routine manual occupations, which in most cases means a decrease in terms of both status and salary. Finally, some of the shrinking job opportunities in routine work cannot immediately be absorbed by labor markets and lead some routine workers to become unemployed. Losing a job outrightly eliminates both the financial and the psychological benefits of employment.

## **Political Reactions to Occupational Transitions**

The strongly concentrated exposure to non-human competition by robots and smart software gives rise to two related but distinct notions of losing out among routine workers. The first, absolute decline, is concerned with the consequences of unfavorable job transitions in a narrow sense and deals with the material implications of negative income changes or redundancy. The second, relative decline, is not necessarily related to individual transitions but to broader changes in the social hierarchy and the perception of being on the unfavorable side of modernization. Jobs have meaning beyond the income they provide. As an "unintended though inevitable" consequence (Jahoda, 1982, p. 39) of its main purpose, employment is also a source of psychological well-being by offering collective purpose and

social status. People strongly care about being valued by others and social status is known as a powerful motive behind individual behavior (Ridgeway, 2014).

The psychological benefit someone derives from a job strongly varies with its quality and esteem. Technological change severely alters the employment structure and hence the relative importance and value attached to different kinds of work. Being traditionally respected members of the lower middle class, routine workers increasingly find themselves in an environment of structural decline. As a consequence of a decreasing demand for routine jobs and sensational media reporting on their soon extinction, the importance and esteem of this kind of work has strongly suffered in the age of automation. The familiar sense of linear progress in the past clashes with insecure future prospects and shatters the idea of ever-ongoing social upward mobility (Mau, 2015; Nachtwey, 2016). The predictable industrial modernity gave way to a post-industrial risk society where traditional family arrangements, lifetime employment and secure retirement are no longer taken for granted (Beck, 1986). While for some, the liberation of the more rigid social and economic rules might be empowering, for others, the departure from inherited traditions and beginning of a new era of technological innovation rather creates a sense of isolation, alienation and discomfort (Ekberg, 2007).

Consequently, routine workers have to cope with parallel challenges to both their material and psychological well-being. Which attitudinal reactions should we expect? Absolute decline and economic vulnerability has been shown to increase demand for redistribution, a strong social safety net and an encompassing, generous welfare state either as direct compensation for economic hardship or as an insurance against probable future income loss (e.g. Baldwin, 1990; Iversen & Soskice, 2001; Rehm, 2009; Häusermann, Kurer & Schwander, 2015; Gidron & Mijs, 2019). Relative decline, in contrast, which is much more related to concerns about social status than about material hardship, produces reactions that transcend economic or welfare demands. A rich body of work in social psychology has implicated threat and status anxiety in the development of socially conservative or even authoritarian character traits as a general response to fear of uncertainty (e.g. Wilson, 1973; Feldman & Stenner, 1997; Jost, Glaser, Kruglanski & Sulloway, 2003). A related literature has argued

that threatens to the perceived value of an ingroup ("group esteem threat") negatively affects members' self-image and might create hostility towards outgroups that are seen as competitors in the social hierarchy (e.g. Riek, Mania & Gaertner, 2006). Typically, comparably higher status groups seek to derogate comparably lower status groups as a strategy of comparative status enhancement (Küpper, Wolf & Zick, 2010).

It stands to reason that the two kinds of decline and the associated attitudinal response suggest very different policy demands. Voters who experience material hardship created by absolute decline become dependent on state support and should thus have a strong interest in a generous welfare state to cushion the economic downfall and encompassing measures to support their re-entry in the labor market. Voters who primarily suffer from status anxiety created by relative decline are more likely to look for propositions that promise to maintain (or reinstall) their place in the social hierarchy.

The point of the matter, however, is that these distinct policy demands are hardly on the same partisan menu. While support for a strong and generous welfare state clearly suggests support for left parties, the less tangible demands related to status anxiety (conservatism, authoritarianism, status enhancement vis-a-vis outgroups) are much more likely to be satisfied by socially conservative parties on the right (Mutz, 2018) – and in particular by right-wing populist parties with an emphasis on the values and virtues of an idealized past (Andersen & Bjørklund, 1990; Oesch, 2008; Bornschieer, 2010; Rydgren, 2013; Gest, Reny & Mayer, 2017; Steenvoorden & Harteveld, 2018). As a consequence, there is no single party that offers credible and satisfying remedies against the parallel challenges routine workers face in times of automation.<sup>2</sup> Instead, they have to balance and *prioritize* demands with respect to economic insecurity and status anxiety. The main argument of this paper is that occupational trajectories are key to understanding the relative salience of these two demands.

---

<sup>2</sup>At first sight, so called welfare chauvinist parties might seem an option to bridge competing demands. However, it is unlikely for voters with a *primary* demand in a strong welfare state to support such parties. The left is still a much more credible supporter of a generous social safety net. If, however, voters have a *secondary* preference for social security beyond their primary concerns about status maintenance, welfare chauvinist parties offer a very attractive policy package.

Survivors are the group threatened but not (yet) hit by transforming labor markets: they cling to middle-range income routine jobs and therefore largely safeguard the economic benefits of employment. In purely economic terms, routine workers are clearly not the worst-off social segment in post-industrial society (see also Bornschier & Kriesi, 2013). However, the gradual reduction in demand for routine work in times of automation goes hand in hand with dwindling esteem for these occupations and threatens their societal recognition, which has long been an essential feature of ordinary work (Lamont, 2018). "Surviving" in routine work is thus first and foremost an experience of *relative* decline in societal position, which highlights status anxiety, activates traditionalist predispositions, and makes socially conservative politics salient (Feldman & Stenner, 1997).<sup>3</sup>

Right-wing populist parties are expected to be the most successful political actor appealing to these sentiments of regretting bygone times. What they offer is not primarily relief from economic stress but remedies against status anxiety by promoting the values of an idealized past where routine workers were a valued and crucial pillar of society. What differentiates them from left-authoritarian parties that might purport a similarly nostalgic worldview is their derogative rhetoric towards migrants as well as "undeserving" or "lazy" parts of the native population, both of which offer an obvious lower-status target at which to direct hostility in an attempt of comparative status enhancement.

*H1a: Right-wing populist parties attract survivors in routine work and transitions out of routine work reduce the probability to vote for this party family.*

In the absence of a right-wing populist party, we expect traditional conservative parties to act as a second-best option for survivors in routine work. Although not promoting the restoration of traditional order as aggressively as right-wing populists, conservative parties are credible advocates of old-established values and expected to be an attractive choice

---

<sup>3</sup>Moreover, the "last-place aversion" theory suggests that concerns about one's relative position in the social hierarchy might depress demand for redistribution even among citizens who, in theory, should be supportive (Kuziemko, Buell, Reich & Norton, 2014). This is due to concerns that welfare might disproportionately benefit lower-status groups, which counteracts the goal of relative status enhancement. Accordingly, support should decrease in particular with respect to redistributive programs that threaten to upset status hierarchies (Suryanarayan, 2019). Although this literature focuses on poor voters rather than the lower-middle class, it is conceivable that similar mechanisms not only reduce the salience of welfare programs but also change attitude towards such policies among survivors in routine work.

for routine workers with an interest in the status quo ante. Indeed, a positional mapping of different party families underlines that conservative parties are by far the fiercest defendants of traditionalist values among mainstream parties (see Figure A1).

*H1b: In the absence of a right-wing populist party, mainstream conservative parties attract survivors in routine work and transitions out of routine work reduce the probability to vote for this party family.*

These hypotheses imply that it is relative rather than absolute decline that determines support for culturally conservative parties. What about actual decline, then? For dropouts, i.e. former routine workers who have been made redundant, the threat of contracting employment opportunities indeed materializes. Fear turns into experience, so to speak, which drastically alters the most pressing needs. Once unemployed, actual scarcity of material resources rather than status anxiety is the most salient problem. We expect dropouts to react with an economic response, thus moving away from socially conservative parties and instead supporting the left, which traditionally and credibly promotes a generous social safety net. Based on Dutch panel data, Wiertz & Rodon (2019) provide evidence in line with this hypothesis.

A second likely response is political abstention. As material resources are a well-known prerequisite for political participation, now-unemployed dropouts might also increasingly stay away from the ballot box (Verba & Nie, 1972). In the light of adverse economic conditions resulting from the loss of labor income, individuals might prefer to spend their scarce resources on "holding body and soul together" than on "remote concerns like politics" (Rosenstone, 1982, p. 26).

*H2a: Dropouts have a higher probability of supporting left parties than survivors.*

*H2b: Dropouts have a higher probability of political abstention than survivors.*

The political reactions among the remaining two groups, upgraders and downgraders, are less clear-cut and the treatments arguably weaker compared to job loss. Upgraders were able to escape the squeeze in the middle for the better and find safer and presumably better-

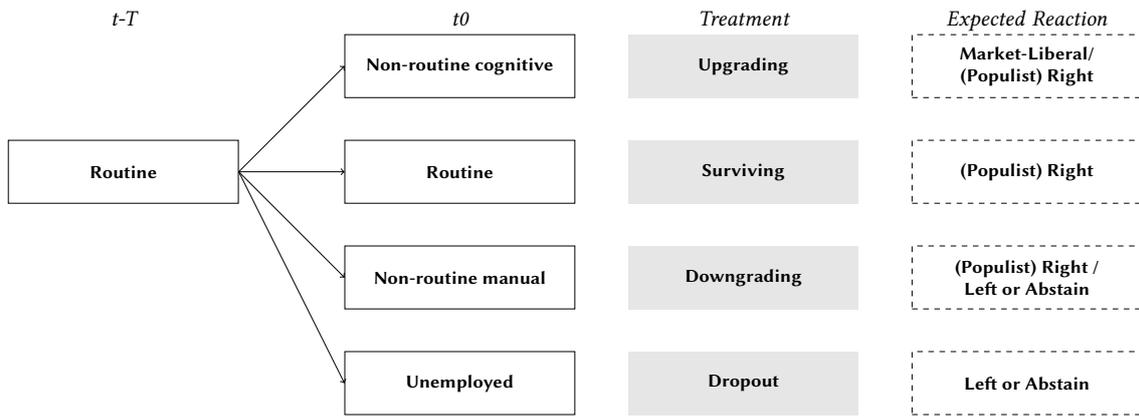

FIGURE 1: Theoretical Framework

paid work in non-routine cognitive occupations. This subgroup therefore experienced the bright side of a market-based allocation of jobs and might be more likely to vote for parties promoting free markets and limited government interventions. Downgraders, on the other hand, experienced a certain decline in status and, most likely, material resources but they were able to remain in the labor force and uphold at least some labor income and economic independence. A priori, it is not obvious which of these counteracting processes dominate their political response. Moreover, formulating theoretical expectations for upgraders and downgraders is complicated by the so called gradient-constraint hypothesis developed in social mobility studies. It suggests that individuals who move between occupational groups will differ in behavior from their class of origin as well as from their class of destination and instead form preferences that lie somewhere in between (Lahtinen, Wass & Hiilamo, 2017; Ares, 2017). Hence, we only have weak theoretical priors with respect to routine workers who upgrade or downgrade and treat the issue as an empirical question.

## Empirical Strategy

### Data and Operationalization

Individual-level panel data with detailed information on respondents' occupation spanning over a reasonably long time period are an essential prerequisite to study the questions at

hand. We thus made an effort to collect all European household panel surveys that meet these conditions, combine all available waves and harmonize the coding of key indicators over time and between datasets. This procedure results in a large comparative, longitudinal micro-level data set including Germany, Switzerland and the United Kingdom and covering the time span of the late 1980s until now (see Table 2).

The three cases at hand provide valuable variation in institutional context and party system, which allows us to test our hypotheses under a variety of circumstances and enhances credence in the external validity of the results. Switzerland provides the largest number of parties and is characterized by the presence of a strong right-wing populist party throughout the entire time period under study. Furthermore, the so-called consensus system traditionally involves all large parties, which makes preference-based vote choice plausible and reduces the probability of vote choice based on non-ideological patterns of retrospective economic voting. The United Kingdom has long been dominated by two large parties, facilitated by its majoritarian model of democracy. However, the recent rise of UKIP makes it possible to test the right-wing populism hypothesis in a different institutional context. We would expect lower baseline probabilities of support for non-mainstream parties due to strategic considerations in a first-past-the-post system but similar patterns of changing support as a reaction to occupational transitions. The proportional election system and diverse party supply in Germany, too, offers various political options to voters with one crucial difference: the absence of a right-wing populist party.<sup>4</sup> Just as the UK before 2013, this constellation will allow to test whether conservative parties indeed serve as second-best option for voters in an increasingly gloomy occupational environment of routine work.

The most important variable for the present analysis is occupational task group. Following the influential Autor-Levy-Murnane model (2003), each occupation is classified into one task group  $j \in \{C, R, M\}$ , i.e. non-routine cognitive, routine and non-routine manual. This classification relies on detailed occupational dictionaries that describe the main activities

---

<sup>4</sup>This situation is changing rapidly with the the rise of the *Alternative fuer Deutschland* (AfD), which has been founded in April 2013 as an anti-Euro party and continuously morphed into a typical right-wing populist party. Unfortunately, the very low number of respondents who indicate AfD support in recent waves makes it impossible to test H1a in Germany because key assumptions of the estimation model are violated (details below).

required to perform a job. We largely build on Cortes' (2016) grouping, which is based on US Census Occupation Codes (COC), which we have translated into an analogous grouping based on ISCO four-digit codes. Table A1 in the appendix provides details on the coding.

This grouping into three task groups  $j \in \{C, R, M\}$  plus the additional option of unemployment  $U$  yields a straightforward analytical framework to study occupational transitions (see Figure 1). A "survivor" in routine work is a respondent with  $j_{i,t} = j_{i,t-p} = R$ , where  $p$  denotes the most proximate previous observation. Surviving in routine work will serve as a reference category in the empirical models. Upgraders are individuals who have been classified as routine worker  $R$  in  $t-p$  but fall into the category of non-routine cognitive work  $C$  in  $t$ . The same logic applies to downgraders and dropouts. From these individual occupational transitions, we create the central explanatory variable, a multi-valued treatment  $D_{i,t}$ .

$$D_{i,t} = \begin{cases} 0, & \text{if } j_{i,t} = R \wedge j_{i,t-p} = R \\ 1, & \text{if } j_{i,t} = C \wedge j_{i,t-p} = R \\ 2, & \text{if } j_{i,t} = M \wedge j_{i,t-p} = R \\ 3, & \text{if } j_{i,t} = U \wedge j_{i,t-p} = R \end{cases}$$

The dependent variable, vote intention, varies between countries and is created from the specific items in the respective data source (see Table A2 in Appendix). It should be noted that the independent questionnaires of the three data sources result in slightly differing operationalizations of the dependent variable, in particular with respect to abstention.

Given the focus of this study, we restrict the sample to respondents who at some point in their employment history hold a routine job. The final data set consists of individuals who have been in routine work in  $t-p$  and who are in one of the four previously defined occupational states  $j \in \{C, R, M, U\}$  in  $t$ . An individual contributes multiple observations to the sample, especially if s/he remains in routine work. The sample is further restricted to individuals of age 18 or more but younger than 65 who are eligible to vote (i.e. have citizenship of the respective country).

TABLE 2: Data Sources and Final Sample Size

Country	Data Source	Time Span	Sample
Switzerland	Swiss Household Panel (SHP)	1999 - 2014	8'871
Germany	Socio-Economic Panel (SOEP)	1989 - 2016	22'481
UK	British Household Panel Survey (BHPS)	1991 - 2008	24'481
	Understanding Society (UKHLS)	2009 - 2015	

## Dynamic Causal Inference

Personal and contextual characteristics determine the likelihood and direction of a transition out of routine work. The standard approach to correct for selection is controlling for confounders. However, applied to dynamic processes like occupational trajectories, controlling itself introduces bias if confounders change over time and are potentially affected by previous treatment. For example, losing a routine job and becoming unemployed is more likely in some regions than in others. Insofar, region is a *predictor* of occupational transitions. However, unemployment then perhaps forces this person to move to another region of the country, which means that region is also a *consequence* of an occupational transition and the new place of residence is likely to influence both future occupational transitions as well as future political preferences. In essence, in a dynamic longitudinal analysis, such time-varying confounders are pre-treatment and post-treatment variables *at the same time* (Blackwell, 2013).

With conventional (fixed-effects) regression or matching methods, the researcher is left with an uncomfortable trade-off: either conditioning on the time-varying confounder, thus getting rid of omitted variable bias at the cost of potential post-treatment bias, or dropping the confounder, which avoids post-treatment bias but induces omitted variable bias. Marginal structural models (MSM) have been suggested as a hedge against this dilemma. Originally introduced in biostatistics (Robins, 1999; Robins, Hernan & Brumback, 2000), the value of MSMs for the frequent occurrence of dynamic treatments in social sciences has been emphasized in recent contributions (Blackwell, 2013; Bacak & Kennedy, 2015; Imai & Ratkovic, 2015; Blackwell & Glynn, 2018).

Three steps are involved in the estimation of a MSM.<sup>5</sup> The first step is concerned with the treatment model. How likely is an individual to receive, e.g., treatment A or B, that is to upgrade or downgrade in the occupational structure? As we are dealing with observational data, individual probabilities of treatment are unknown and have to be estimated empirically. Treatment assignment at each time point is modeled conditional on theoretically derived covariates (i.e. known determinants of treatment assignment) and the observed past, including the treatment history of a respondent.

Second, for every respondent in the sample, we create a weighting variable for each time point  $t$  that is equal to the inverse product of the calculated conditional probabilities at  $t$ . Re-weighting observations with the inverse individual probability of receiving treatment at  $t$  creates a pseudo-population where dynamic selection is eliminated, i.e. where treatment assignment is unaffected by confounding. A person living in a region with high unemployment risk at  $t$  has a higher probability to get treatment C, i.e. losing a routine job. Weighting these respondents by the inverse of a high probability will downweight their influence and help achieve balance in the sample, that is, reduce confounding based on place of residence.

As a last step, we run the outcome model: To estimate the causal parameter of a MSM, we perform a weighted linear regression of the dependent variable, vote intention, on the multi-valued treatment variable capturing occupational transitions out of routine work. Importantly, this model avoids conditioning on time-varying covariates as confounding is accounted for via weighting instead of controlling. In contrast to standard regression or matching procedures, we never explicitly condition on confounders in the outcome model and thereby eliminate the threat of introducing post-treatment bias due to covariates that dynamically evolve over time (Blackwell, 2013).

For the specification of the treatment model (Step 1), expert knowledge on the determinants of occupational transitions is key. Fortunately, a rich body of work in labor economics and economic sociology provides clear guidance in that regard. First of all, studies on local la-

---

<sup>5</sup>Robins and colleagues (1999; 2000) provide a formal discussion. Blackwell (2013) offers a theoretical and substantive introduction to political science contexts.

bor markets have emphasized a strong spatial component to occupational change, driven separately by globalization and technological progress (Autor, Dorn & Hanson, 2013). Regarding individual traits, Cortes (2016) shows that the sorting mechanism out of routine work depends on ability and skills: Especially routine workers with remarkable cognitive resources face a realistic chance of an occupational upgrade. Furthermore, women appear to be much more likely than men to leave declining routine jobs but often end up in lower-paid non-routine jobs (Murphy, 2014). Age also matters: Especially young routine workers climb the occupational ladder while prime age and older workers remain in the contracting occupations of routine employment (Autor & Dorn, 2009). In addition, unions are likely to play a role regarding occupational transitions and employment protection. Members of a trade union might be less vulnerable to unemployment and potentially more stably embedded in their current job, thus making transitions less likely. Hence, the five most important determinants of the sorting mechanism appear to be region, education, gender, age and union membership. This is the core of the treatment model. Variable selection is justified by model fit (AIC), which is best in the full treatment model, i.e. better than in any specification omitting any of the core variables.

In addition, MSMs exploit the longitudinal data structure and take into account the entire treatment history of an individual. We rely on a combination of a one-period lagged treatment variable and the cumulative treatment history (share of years treated) of each respondent. Year dummies are included to adjust for period effects. A multinomial model then regresses the multi-valued treatment  $D_{i,t}$  on the covariates and treatment history in order to generate individual, dynamic weights for each respondent.<sup>6</sup>

MSMs properly adjust for both selection into treatment and measured confounding if the treatment model satisfies the following four assumptions: consistency, exchangeability, positivity and no misspecification (Cole & Hernán, 2008). We provide a more detailed discussion of the validity of these assumption in the supplementary material along with

---

<sup>6</sup>As recommended by the literature, weights are stabilized by treatment history and time-invariant covariates (van der Wal & Geskus, 2011). The sensitivity analysis in the supplementary information to this article demonstrates the superiority of this approach to non-stabilized weights.

an extensive sensitivity analysis of the baseline model, which demonstrates that the results do not hinge on the specific modeling choices of the main analysis.

## **Results**

### **Occupational Transition Patterns**

The first part of the empirical section exploits the richness of the comparative longitudinal data to report some descriptive evidence on country-specific patterns of occupational change and the relative frequency of routine worker's distinct employment trajectories. Figure 2 describes country-specific patterns of occupational change and reveals remarkably distinct employment structures with one striking commonality: The decline of routine jobs. Switzerland has long been characterized by a strong concentration of jobs in highly skilled and specialized non-routine cognitive occupations, a trend that has been reinforced during the last decade. Routine jobs have been less important already at the beginning of the observed period but continued to decline over time. The longer time span available for Germany, in comparison, reveals the dominant position of routine jobs in the 1980s – as well as their remarkable demise over time. At the same time, Switzerland and Germany display a strong and persistent trend of occupational upgrading evidenced by an ever-increasing share of work in demanding analytical and/or interactive occupations.

The employment structure in the United Kingdom has evolved rather differently. A similar decrease in routine work and a moderate increase in high-skilled jobs is accompanied by enduring job growth at the lower end of the skill spectrum. These patterns reflect earlier findings, which concluded that Britain's hollowing of the middle goes hand in hand with a persistent growth in low-skilled service jobs, leading to a more pronounced polarization of the employment structure (Goos & Manning, 2007).

As mentioned above, long-term changes in the employment structure are heavily influenced by compositional effects and do not necessarily imply analogue patterns of individual-

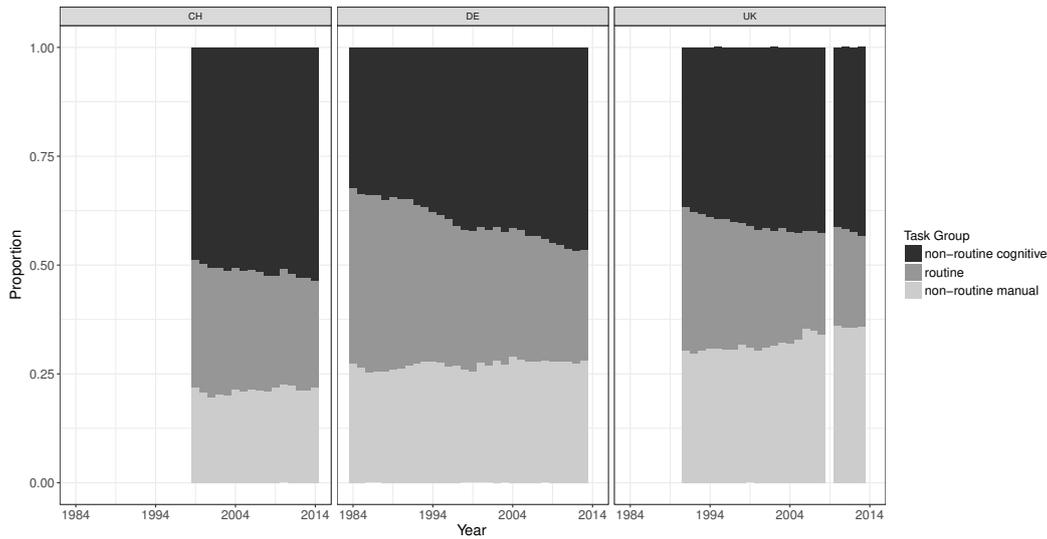

FIGURE 2: Relative Share of Task Groups over Time

level transitions (Cortes, 2016; Kurer & Gallego, 2019). Table 3 shows actual transition rates of (former) routine workers in our sample and confirms this notion. Despite the strong decline in the aggregate, on the individual level, survival in routine work is not uncommon at all. A large majority of routine workers also retires as routine workers.<sup>7</sup> Still, between roughly 10 and 20 percent switch into either non-routine cognitive or non-routine manual jobs – or ended up unemployed. Transitions are comparably rare in Switzerland but more frequent in Germany and, most of all, in the UK’s more flexible labor market. In terms of the transition’s direction, upgrading into more sophisticated non-routine cognitive jobs is by no means an impossible exit route for routine workers – despite different requirements with regard to skills and, often, formal education. Downward transitions into non-routine manual jobs occur only slightly less often. The least frequent trajectory for routine workers is to become unemployed.

<sup>7</sup>However, the underlying coding puts the numerical dominance of remaining in routine work into perspective: An individual who has been working in routine work for five years and then upgrades to non-routine cognitive work will contribute four observations to the survivor category and one observation to the upgrader category. Other individual-level studies report somewhat higher shares of transitions out of routine work in the US (Cortes, 2016) and the UK (Kurer & Gallego, 2019) but also conclude that a clear majority of routine workers “survives” in their jobs.

TABLE 3: Occupational Transition Patterns

	CH	DE	UK
	%	%	%
Upgraders	4.5	5.1	10.2
Survivors	90.8	87.0	77.5
Downgraders	3.2	4.1	8.8
Dropouts	1.4	3.8	3.4

## Employment Trajectories and Vote Intention

The next step is to link these different occupational trajectories to individual political responses. Tables 4-6 report the baseline probability to support the party indicated in the top row among survivors in routine work who, in line with the theoretical reasoning above, represent the reference category. The following three rows then display the effects of the three different treatments, i.e. upgrading, downgrading or dropping out.

The baseline probabilities in the first row confirm our expectation that right-wing populist parties (RPP) are successful in mobilizing survivors in routine work. Although large parts of routine work belong to the traditional core constituency of the Left, RPPs have been proved a strong competitor for these votes. In the presence of an influential right-wing populist party, the traditional preserve of the Left turns into a "contested stronghold" (Oesch & Rennwald, 2018). Evidently, traditional mainstream conservative parties are less successful in mobilizing among the former core constituency of the Left. With respect to alternative political options, market-liberal parties are a much less likely choice for routine workers and self-reported abstention is comparatively rare in Switzerland and Germany, while British data seem to produce more realistic estimates of nonvoting.<sup>8</sup>

How do transitions out of routine work affect vote intention? The coefficients in the following tables report the change in the probability to vote for the specific party of the respective model if an individual switches from the reference category, routine work, into one of the three above-defined alternatives. The most important finding is that a transi-

<sup>8</sup>The operationalization of abstention with Swiss data is less than ideal as the household survey does not report turnout directly, see Table A2.

tion from routine work into unemployment results in a strong and consistent decline in support for the most conservative party in all three countries. The results for Switzerland and the UK provide consistent evidence that it is indeed primarily "surviving" in routine work that fuels support for RPPs, while materialized economic hardship, i.e. a transition into unemployment, immediately and substantially reduces this support. Former routine workers' probability to vote for the Swiss Peoples Party or the United Kingdom Independence Party, respectively, declines substantially once they lose their job and are unable to find another one.

In the absence of a RPP, the results show similar patterns of voting behavior with respect to conservative parties. Support among now-unemployed routine workers decreases substantially in Germany as well as in the UK, where the Conservative Party has not faced competition from the Right until 2013. Insofar, conservative parties seem to act as a second-best solution to satisfy routine workers' desire for the status-quo ante. The voting behavior of dropouts supports the main claim of this paper: It is fear of social decline rather than the actual experience of economic hardship, which drives support for parties who seek to "turn back the clock" (Gest et al., 2017) and promote socially conservative values.

Results from a Marginal Structural Model based on stabilized inverse-probability of treatment weights. Treatment model covariates beyond individual treatment history are region, education, age, gender, union member and year dummies. Robust standard errors clustered by individual in parentheses. Data source: German Socio-Economic Panel (SOEP v33), pooled data between 1983 and 2016. Abstention model is based on years 2005 and 2009 only.

While the first model offered evidence that transitions out of routine work indeed reduce support for right-wing populist or conservative parties, the following three models give an indication of which parties are supported instead. The picture with respect to dropouts

is very consistent and goes in two different directions.<sup>9</sup> Dropping out of the labor market either produces an economic response that leads to increasing support for left parties who stand for a strong social safety net. A further sub-analysis for Germany shows that this effect is particularly pronounced with respect to far-left parties ("Die Linke") with an especially fierce position on defending a generous welfare state. The second significant political reaction of dropouts is growing political disenchantment. As a consequence of becoming unemployed, abstention rates among former routine workers increase between 6.1 (UK), 8.2 (Switzerland) and almost 15 percentage points (Germany).

As expected, the results for upgraders and downgraders are less consistent and offer mixed evidence. Upgraders in Switzerland increasingly support the Social Democrats, which might be explained by the strongly changing class basis of the Swiss Social Democratic Party, whose constituency is increasingly dominated by high-skilled and relatively well-off citizens (Rennwald, 2014). In contrast, German and British upgraders instead increasingly support market-liberal parties, which makes sense given that they managed to leave the squeezed middle for the better. In the UK, they vote for both the conservatives as well as the Liberal Democrats, in Germany primarily for the FDP. The results for downgraders are generally weak. Apart from lower support for market-liberal parties in Switzerland and the conservatives in the UK, there is no systematic pattern that differentiates the voting behavior of routine workers who remain in routine work and those who are forced to downgrade into lower-skilled non-routine jobs. Despite the experience of an occupational downgrade, these individuals still largely share the political preferences of routine workers. This non-effect has substantive meaning: Right-wing populist parties enjoy ongoing or even increasing success in spite of the steadily shrinking electoral weight of routine workers. Downgraders seem to partly compensate for shrinking share of RPP voters in routine jobs: Displaced into lower skilled service jobs, former routine workers still support the same parties.

---

<sup>9</sup>The effects for Switzerland with by far the lowest number of transitions into unemployment in the final model are less precisely estimated with p-values of 0.078 and 0.085, respectively.

Taken together, socially conservative parties find strong support among "survivors" in routine work, who share a bright past and rather bleak future prospects — but hold on to their dwindling position in the labor market. Contrary to what is often assumed, absolute economic hardship does not appear as a driver of support for socially conservative or right-wing parties. Effectively dropping into unemployment increases the probability to vote for pro-welfare parties or, even more likely, to abstain from the ballot box altogether.

## **Robustness**

The presented results adjust for confounding and post-treatment bias under four assumptions of consistency, exchangeability, positivity and no misspecification. There is no empirical test to verify these assumptions, but credibility in the presented estimates can be increased by the means of sensitivity tests (Cole & Hernán, 2008). The supplementary information to this article provides extensive robustness checks to increase our confidence in the stability of the presented results. Particular emphasis is given to the specification of the treatment model. Two aspects are examined more closely: the selected predictors of treatment assignment and the exact estimation of the inverse-probability weight, a particularly sensitive aspect of marginal structural models (Imai & Ratkovic, 2015; Blackwell & Glynn, 2018). A detailed sensitivity analysis demonstrates the robustness of the estimates in the baseline model. The effect of becoming unemployed on voting for a right-wing populist party hardly at all changes across the seven different specifications examined in this sensitivity analysis. The size of the effect remains within a narrow range of about two percentage points and is strongly significant in each model. This increases confidence that the presented changes in the probability to support a specific party are caused by individual occupational transitions out of routine work.

In addition, we demonstrate that the findings are robust to an end-of-study outcome model, perhaps the most frequent application of MSMs, and that the results in the UK hold if we restrict the sample to BHPS respondents (i.e. excluding respondents that entered the study only in 2010 with the start of the broader UKHLS sampling).

## From Automation to Status Decline to Voting

The above analysis provides evidence that support for right-wing populist parties is not primarily driven by the experience of economic hardship. To the contrary, losing a routine job and becoming unemployed consistently *reduces* support for conservative and right-wing populist parties. We have argued that survivors in routine work experience relative rather than absolute economic decline, which increases the salience of social conservatism and outgroup hostility vis-a-vis welfare state politics. A limitation of the analysis is that it does not directly assess the proposed mechanism, i.e. that susceptibility to automation creates status anxiety, which in turn fuels support for right-wing populist parties. The employed panel data are very limited with respect to items asking respondents about subjective perceptions and none of them provides questions about perceived social status.

We address this shortcoming by providing illustrative evidence from two additional data sources. The aim is twofold. First, we seek to underscore our basic narrative of a relative decline in subjective social status among routine workers compared to non-routine groups over time. To this end, we employ data from the International Social Survey Programme (ISSP), which is uniquely suited for this purpose because it started already in the 1980s and some waves included otherwise rarely asked questions on subjective social status. At least on the aggregate level, this combination allows studying the evolution of subjective *relative* positions in the social hierarchy over time. Second, we wish to provide support for the suggested underlying mechanism, which runs from exposure to automation via status decline to support for right-wing populist parties. To the best of our knowledge, no existing individual-level data set covers all of these issues. We therefore added several specific questions to an original survey that was fielded in eight Western European countries in late 2018.<sup>10</sup>

Figure 3 shows the results of the over-time analysis of relative social status based on ISSP data for the same countries as in the previous analysis. The specific survey item asks respondents to indicate their perceived place on the social ladder, where some groups tend

---

<sup>10</sup>Denmark, Germany, Ireland, Italy, Netherlands, Spain, Sweden, United Kingdom. More details on sampling and dataset are provided in the supplementary information.

to be towards the bottom (0) and some towards the top (10) of society. As expected, routine and non-routine manual workers have on average lower levels of subjective status compared to high-skilled non-routine cognitive workers. However, the interesting aspect of Figure 3 is how these perceptions change relative to each other over time. Whereas routine workers felt significantly closer towards the top of the societal scale than non-routine manual workers in 1987, this difference almost disappears in the following 30 years. The results are substantively similar with a non-linear specification of the time trend (see Supplementary Information).

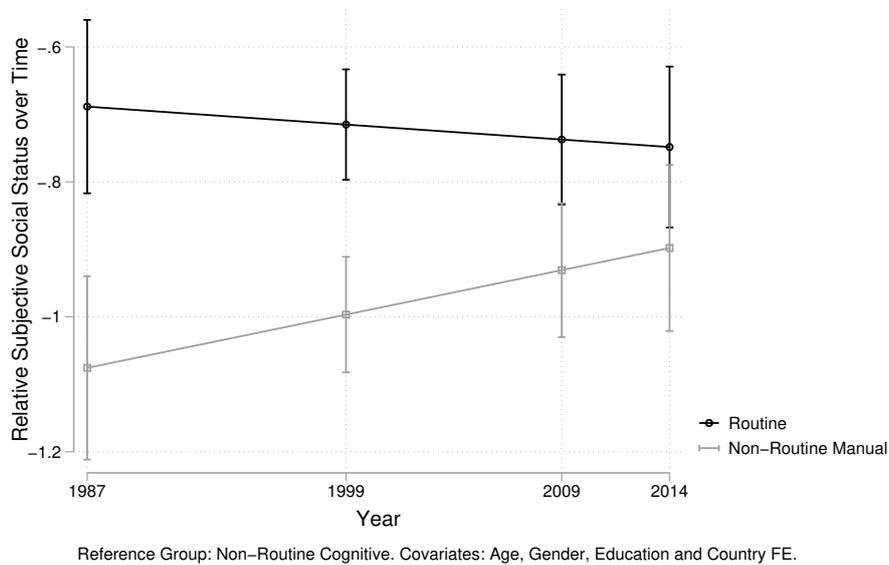

FIGURE 3: Marginal Effect of Task Group on Subjective Social Status over Time

Are such differences in subjective social status related to technology-induced occupational change and do they affect the individual propensity to support right-wing populist parties? Figure 4 plots results from a series of analyses based on our original survey data.<sup>11</sup> Panel A confirms a basic assumption of this paper, namely that objectively higher rates of automation risk among routine workers are in fact reflected in individual perceptions. We asked respondents about the probability that their job will be automated within the next 10 years. Routine workers indeed estimate this risk to be significantly higher than workers employed in either of the two non-routine groups.

<sup>11</sup>Full regression tables of all analyses are provided in the supplementary information to this article.

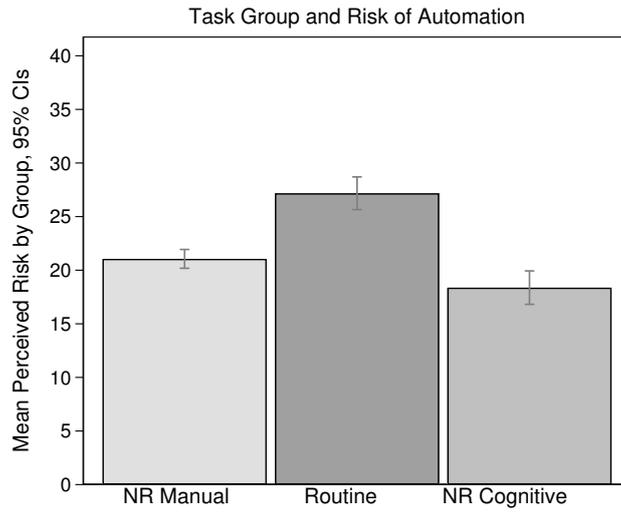

The second panel then looks at the relationship between risk of automation and changing positions in the social hierarchy. We tried to overcome the lack of longitudinal variation in a cross-sectional survey by explicitly asking respondents about *change* (compared to their parents' generation) rather than *level* of subjective social status. The results of the underlying ordered logit models, which include individual-level controls (gender, age, education, and employment status) and country-fixed effects, are displayed as predicted probabilities of higher/same/lower status conditional on perceived risk of automation. As expected, more pessimistic labor market prospects are associated with more negative perceptions of social status. The higher (lower) a respondent estimates her risk of replacement by new technologies, the higher his probability of perceived downward (upward) mobility.

Panel c, finally, brings the argument full circle by examining the relationship between status decline and party choice. We display predicted probabilities from a linear probability model including the same covariates as before. In line with a recent evaluation by Gidron & Hall (2017), there is an unambiguously positive association between individual perceptions of status decline and support for right-wing populist parties.<sup>12</sup> This correlation is robust to alternative model specifications (logit), different coding of the dependent variable as well as the exclusion of potential outliers (see Supplementary Information).

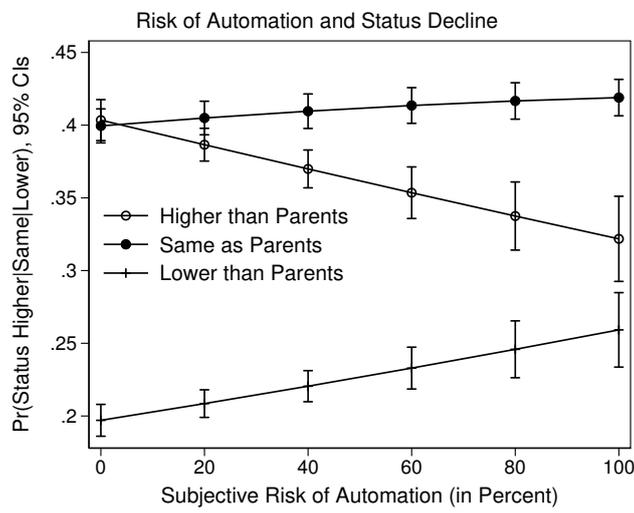

Although this additional evidence from cross-national data is not directly linked to the above panel analysis, it still offers additional insights into how occupational change, subjective social status and vote choice relate to each other. We conclude that (a) routine workers' social status has slightly decreased in absolute terms but especially in relative terms compared to lower-status groups, that (b) these changes in perceptions of social hierarchies are related to subjective labor market prospects and susceptibility to automation, and that (c) perceived status decline is a relevant covariate of supporting right-wing populist parties. Taken together, the presented observational evidence supports the notion that survivors in routine workers are conscious about their deteriorating position in the

---

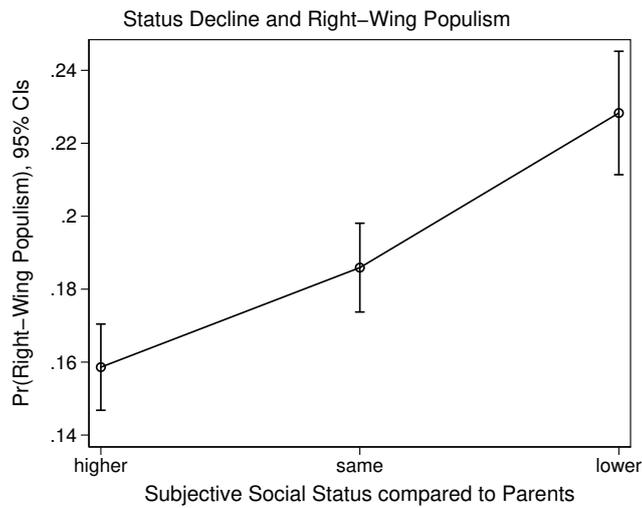

<sup>12</sup>The following parties are coded as right-wing populist: DK: Danish People's Party; DE: Alternative for Germany; IT: Lega Nord; NL: Party for Freedom; SE: Sweden Democrats; UK: United Kingdom Independence Party. Ireland and Spain are thus not included in this analysis.

(A) Risk of Automation

(B) Status Decline

(c) Right-Wing Populism

FIGURE 4: Tracing the Mechanism

social hierarchy and that this experience triggers political demands that are apparently best satisfied by the promises of right-wing populist parties.

We underscore this latter point by a final auxiliary analysis that addresses the question whether and to what extent radical left parties are able to mobilize voters suffering from status anxiety. We argued above that the combination of social conservatism that promotes the values of an idealized past and the hostile attitude towards lower-status groups offer the most attractive package to routine workers who are doing alright in economic terms but experience relative decline in the social hierarchy. This expectation is indeed borne out by the data. While, in the overall sample, there is also a positive correlation between status decline and support for radical left parties, routine workers feel much more drawn towards the right. The overall level of support as well as the strength of the correlation is much higher for radical right as opposed to radical left parties. Not unexpectedly, there seems to be a common theme among radical non-mainstream parties that attracts voters who are dissatisfied with the status quo. However, when it comes to an anxious lower middle class in search for status enhancement but not in need of economic support, right-wing populist promises are uniquely alluring.

## **Discussion and Conclusion**

Many post-industrial societies have recently been disrupted by unprecedented levels of anti-establishment rhetoric and the rise of new parties that challenge the democratic status quo. This article studies in how far technological change and the associated transformation of the employment structure contribute to this development. We do so by examining the political behavior of routine workers, a large and influential part of the labor force that is particularly exposed to workplace automation. As a core contribution, we disentangle the political implications of *relative* as opposed to *absolute* economic decline.

The gradual but momentous decrease in demand for routine work in post-industrial labor markets provides an ideal setting for this endeavor. We differentiate between, on the one

hand, "survivors" in routine work who manage to cling to their jobs and maintain their mid-range incomes but perceive their relative position in the social hierarchy to be declining. On the other hand, we study political responses among "dropouts", that is former routine workers who have been made redundant by new technology and thus face the material consequences of jobloss. The main finding is that surviving in an environment of structural decline drives support for right-wing populist parties whereas the actual experience of economic hardship immediately and substantively reduces this support.

To be sure, this paper only provides a partial explanation of the widespread success of right-wing populist forces on both sides of the Atlantic. There are certainly other groups beyond routine workers who find the promises of right-wing populist parties appealing and they might do so based on different motives (see, e.g. Kitschelt's (1995) discussion of the *petite bourgeoisie*). And yet, routine workers' strong support of right-wing populist parties demonstrate that the presented argument has considerable traction and might well reach beyond the group considered here. It is not difficult to imagine various additional sources of perceived relative decline and status anxiety in a fast-paced risk society (Beck, 1986). What is more, automation, computerization and machine learning techniques have undoubtedly not yet reached their peak and will continue to transform the world of work in the years to come. Technological change will affect sections of the labor force who have so far been spared from the threat of automation and thus constantly preserve or even enlarge the pool of voters who are receptive to political programs addressing status anxiety. Given the structural roots of the presented findings, there is much reason to expect right-wing populist parties to become a constant feature of the political arena in post-industrial democracy.

What makes this development so fascinating from a political science perspective is the sheer absence of adequate policy reactions. In contrast to other highly salient issues like immigration or free trade, national governments are extremely limited in their options to effectively counter the forces of technological progress. Since it is not actual economic adversity that drives political resentment among relative losers of occupational change, the often proposed policy reaction of "more welfare" in the traditional sense will not help

alleviate their grievances. While there are many good reasons for a strong welfare state, it will most likely not counter the ascent of right-wing populist parties. This important implication seems to be reflected in the sobering findings of a recent study on electoral consequences of social spending by Gingrich (2019). Not unexpectedly, welfare retrenchment is electorally harmful and tends to benefit right-wing populist mobilization. Fetzer (2018) provides similar evidence on austerity and UKIP support. However, importantly, the reverse mechanism (more spending, less populism) is not borne out by Gingrich's data. This asymmetry supports Mudde's (2019) important point that the decline of social democracy and the rise of right-wing populism are not exactly two sides of the same coin — and highlights painfully clearly mainstream parties' limited leeway to compensate relative losers of economic modernization.

Rather than receiving financial support from governments, these voters want their perceived relative decline in the social hierarchy addressed. Right-wing populist have long recognized this. Their programmatic proposal, whether politically viable or not, should not be trivialized as mere populist seduction void of content but should be seen as a political offer to the significantly large part of the population who faces rather bleak prospects and fears social regression. The limited capacity of governments to effectively attenuate political grievances among those adversely exposed to relentless technological progress highlights the strategic disadvantage of responsible center-right or center-left parties in contemporary democracy. It renders post-industrial societies vulnerable to political forces responding to voters on the grounds of less tangible identity politics, which are difficult to counter with mundane, precise and politically feasible policy reactions.

Further research will be needed to answer additional questions triggered by the results presented above. It might be a worthwhile avenue to look more closely into potentially heterogeneous effects of labor market transitions. This paper is based on a parsimonious economic framework, which bundles different types of jobs and individuals within relatively broad task groups. Interesting questions for future research might include differences between blue- and white-collar routine workers or between male and female routine workers. Furthermore, questions of intergenerational mobility might also contribute to

political reactions as the occupational path of life-long employment in routine work becomes increasingly unlikely. How individuals perceive an environment of structural decline clearly depends on many individual and contextual characteristics. Studying these characteristics will further improve our understanding of the political fallout of technological change — a topic that will certainly concern post-industrial societies for some more years.

TABLE A1: Occupation per Task Group

Task Group	ISCO-88
Non-Routine Cognitive	1000, 1120, 1130, 1141, 1142, 1143, 1200, 1210, 1220, 1221, 1222, 1223, 1224, 1225, 1226, 1227, 1228, 1229, 1230, 1231, 1232, 1233, 1235, 1236, 1237, 1239, 1310, 1311, 1312, 1313, 1314, 1315, 1316, 1317, 1318, 1319, 2000, 2110, 2111, 2112, 2113, 2114, 2121, 2122, 2130, 2131, 2139, 2140, 2141, 2142, 2143, 2144, 2145, 2146, 2147, 2148, 2149, 2210, 2211, 2212, 2213, 2221, 2222, 2223, 2224, 2229, 2300, 2310, 2320, 2330, 2340, 2350, 2351, 2352, 2359, 2410, 2411, 2412, 2419, 2420, 2421, 2422, 2429, 2430, 2431, 2432, 2440, 2441, 2442, 2443, 2444, 2445, 2446, 2450, 2451, 2452, 2453, 2454, 2455, 2460, 2470, 3000, 3100, 3110, 3111, 3112, 3113, 3114, 3115, 3116, 3118, 3119, 3121, 3122, 3130, 3131, 3132, 3133, 3140, 3142, 3143, 3144, 3145, 3150, 3151, 3152, 3211, 3212, 3213, 3220, 3222, 3223, 3224, 3226, 3229, 3231, 3232, 3300, 3310, 3320, 3330, 3340, 3400, 3410, 3411, 3412, 3413, 3414, 3415, 3416, 3417, 3419, 3420, 3421, 3422, 3423, 3429, 3432, 3433, 3440, 3441, 3442, 3443, 3449, 3450, 3460, 3470, 3471, 3472, 3474, 3475, 3480
Routine	100, 3430, 3431, 4000, 4100, 4110, 4111, 4112, 4113, 4115, 4120, 4121, 4122, 4130, 4131, 4133, 4141, 4142, 4143, 4144, 4190, 4210, 4211, 4212, 4213, 4215, 4223, 6110, 6111, 6112, 6121, 6129, 6130, 6141, 6152, 6154, 7000, 7110, 7112, 7113, 7124, 7200, 7211, 7212, 7213, 7214, 7215, 7220, 7221, 7222, 7223, 7224, 7230, 7231, 7232, 7233, 7240, 7241, 7242, 7244, 7245, 7311, 7312, 7313, 7321, 7322, 7324, 7330, 7331, 7340, 7341, 7342, 7343, 7344, 7345, 7346, 7410, 7411, 7412, 7413, 7415, 7420, 7421, 7422, 7423, 7424, 7430, 7432, 7433, 7434, 7435, 7436, 7437, 7440, 7441, 7442, 8000, 8100, 8113, 8120, 8122, 8123, 8124, 8139, 8140, 8142, 8143, 8150, 8159, 8160, 8161, 8162, 8163, 8200, 8210, 8211, 8212, 8221, 8222, 8223, 8231, 8232, 8240, 8251, 8253, 8260, 8261, 8262, 8264, 8270, 8273, 8274, 8275, 8278, 8279, 8280, 8281, 8285, 8290, 8340, 9000, 9133, 9150, 9151, 9153, 9160, 9161, 9211, 9300, 9310, 9311
Non-Routine Manual	3221, 3225, 3227, 3228, 4221, 4222, 5000, 5100, 5110, 5111, 5112, 5113, 5120, 5121, 5122, 5123, 5130, 5131, 5132, 5133, 5139, 5140, 5141, 5142, 5143, 5149, 5160, 5161, 5162, 5163, 5169, 5210, 5220, 7120, 7121, 7122, 7123, 7129, 7130, 7131, 7132, 7133, 7134, 7135, 7136, 7137, 7139, 7141, 7143, 8310, 8311, 8312, 8320, 8322, 8323, 8324, 8330, 8332, 8333, 8334, 9100, 9113, 9130, 9132, 9140, 9141, 9142, 9152, 9162, 9312, 9313, 9320, 9330

TABLE A2: Dependent Variable: Operationalization

<b>Switzerland</b>		
<u>variable</u>	<u>pp19</u>	<i>Party choice in case of elections tomorrow</i>
operationalization	RPP	Schweizerische Volkspartei (SVP)
	Cons.	Christlich-Demokratische Volkspartei (CVP)
	Left	Sozialdemokratische Partei (SP); Gruene Partei (GPS); Partei der Arbeit (PdA); Alternative/Solidaritee
	Liberal	FDP.DieLiberalen; Gruenliberale Partei (GLP)
	Abstention	Vote for no party
<b>Germany</b>		
<u>variable</u>	<u>plh0012</u>	<i>Which political party do you support?</i>
operationalization	Cons	Christlich-Demokratische Union (CDU); Christlich-Soziale Union (CSU)
	Left	Sozialdemokratische Partei Deutschlands (SPD); Buendnis Gruene.90; Die Linke
	Liberal	Freie Demokraten (FDP)
<u>variable</u>	<u>plh0003</u>	<i>Voted in last Bundestagswahl (available 2005 and 2009)</i>
operationalization	Abstention	did not vote
<b>UK</b>		
<u>variable</u>	<u>vote3</u>	<i>Which party would you vote for tomorrow</i>
operationalization	RPP	United Kingdom Independence Party (from 2013)
	Cons	Conservative Party
	Left	Labour Party; Scottish National Party; Greens
	LibDem	Liberal Democrats
<u>variable</u>	<u>vote7</u>	<i>Did you vote in [month, year] UK general election? (unbalanced)</i>
operationalization	Abstention	did not vote (vote7==2) OR would not vote for any party tomorrow (vote3==95)

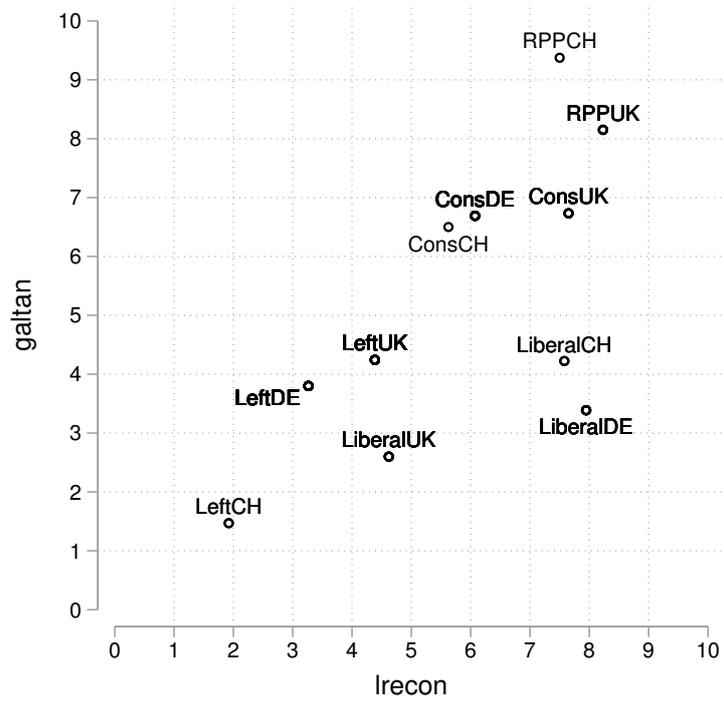

FIGURE A1: Ideological Mapping of Party Families (CHES, weighted by vote share)
